Gullies with Varied Shapes on a Crater Wall

uahirise.org/ESP_023665_1410

This impact crater has gullies incised into its walls on the north and eastern sides. A couple of gullies on the north wall are unusual because a segment in the middle becomes wider than the upslope segment, and then narrows again downslope. This indicates the ground was weaker here and/or that more powerful erosion took place here.
