

An aerial photograph of a Martian crater slope, showing a series of parallel gullies running diagonally across the reddish-brown terrain. The gullies are lighter in color, suggesting they are composed of different material or are more eroded. The overall texture is rough and granular.

MONITORING ACTIVE GULLIES

Gullies are common on steep slopes of many impact craters on Mars. Monitoring them could help scientists better understand the conditions where the gullies are active, and in doing so, help understand how they form.
