

Active Flows on Steep Slopes in Ganges Chasma

ESP_049981_1710

This image covers a steep west-facing slope in southwestern Ganges Chasma, north of the larger canyons of Valles Marineris. We see two distinct flow deposits: lobate flows that are relatively bright, sometimes with dark fringes, and very thin brownish lines that resemble recurring slope lineae (also called “RSL”). Both flows emanate from rocky alcoves.
